The relationship between the expansion of literacy in Judah and composition of biblical texts has attracted scholarly attention for over a century. Information on this issue can be deduced from Hebrew inscriptions from the final phase of the first Temple period. We report our investigation of 16 inscriptions from the Judahite desert fortress of Arad, dated ca. 600 BCE— the eve of Nebuchadnezzar’s destruction of Jerusalem. The inquiry is based on new methods for image processing and document analysis, as well as machine learning algorithms. These techniques enable identification of the minimal number of authors in a given group of inscriptions. Our algorithmic analysis, complemented by the textual information, reveals a minimum of six authors within the examined inscriptions. The results indicate that in this remote frontier fort literacy had spread throughout the military hierarchy, down to the quartermaster and probably even below that rank. This implies that an educational infrastructure that could support the composition of literary texts in Judah already existed before the destruction of the first Temple. A similar level of literacy in this area is attested again only 400 y later, ca. 200 BCE.

Significance

Scholars debate whether the first major phase of compilation of biblical texts took place before or after the destruction of Jerusalem in 586 BCE. Proliferation of literacy is considered a precondition for the creation of such texts. Ancient inscriptions provide important evidence of the proliferation of literacy. This paper focuses on 16 ink inscriptions found in the desert fortress of Arad, written ca. 600 BCE. By using novel image processing and machine learning algorithms we deduce the presence of at least six authors in this corpus. This indicates a high degree of literacy in the Judahite administrative apparatus and provides a possible stage setting for compilation of biblical texts. After the kingdom’s demise, a similar literacy level reemerges only ca. 200 BCE.

The authors declare no conflict of interest.

dissemination of writing, and consequently on the spread of literacy in Judah.

**Algorithmic Apparatus**

One might try to use existing computerized algorithms for automatic handwriting comparison purposes. However, an algorithmic analysis of the Arad corpus via readily available means is hampered by several factors. First, the poor state of preservation of the ostraca (Fig. 2) could not be remedied by existing image acquisition methods (9, 10). Second, the imperfect digital images present a challenge for image segmentation and enhancement methods (11, 12). Finally, recognizing hands via document analysis algorithms is a tantalizing problem even in a modern writing setting (13). Consequently, we developed new methods for image processing and document analysis, as well as machine learning algorithms. These techniques allow us to identify the minimal number of authors represented in a given group of ostraca.

Our algorithmic sequence consisted of three consecutive stages, operating on digital images of the ostraca (see Supporting Information). All of the stages are fully automatic, with the exception of the first, which is a semiautomatic step.

1. **Restoring characters** (see example in Fig. 3; also see Supporting Information and ref. 14)
2. **Extraction of characters’ features**, describing their different aspects (e.g., angles between strokes and character profiles), and measuring the similarity (“distances”) between the characters’ feature vectors.
3. **Testing the null hypothesis** $H_0$ (for each pair of ostraca), that two given inscriptions were written by the same author. A corresponding P value ($P$) is deduced, leveraging the data from the previous step. If $P \leq 0.2$, we reject $H_0$ and accept the competing hypothesis of two different authors; otherwise, we remain undecided.

The end product is a table containing the $P$ for a comparison of each pair of ostraca. Before implementing our methodology on the Arad corpus, it was thoroughly tested on modern Hebrew handwritings and found solid (see Supporting Information for details).

**Results**

Using this computerized procedure we analyzed 16 inscriptions from the Arad fortress (namely, ostraca 1, 2, 3, 5, 7, 8, 16, 17, 18, 20f6

![Fig. 2. Ostraca from Arad (see ref. 6): numbers 24 (A), 5 (B), and 40 (C). The poor state of preservation, including stains, erased characters, and blurred text, is evident. Images are courtesy of the Institute of Archaeology, Tel Aviv University, and of the Israel Antiquities Authority.](image-url)
21, 24, 31, 38, 39, 40, and 111), which are relatively legible and have a sufficient number of characters for examination. Two of the inscriptions (ostraca 17 and 39) are inscribed on both sides of the sherd, bringing the number of texts under investigation to 18. The results are summarized in Table 1. The ostraca numbers head the rows and columns of the table, with the intersection cells providing the comparisons\(^*\) \(P\). The cells with \(P \leq 0.2\) are marked in red, indicating that the two ostraca are considered to be written by different authors. We reiterate that when \(P > 0.2\) we cannot claim that they were written by a single author.

The results allow us to estimate the minimal number of writers in the tested inscriptions. For example, the examination of ostraca 7, 18, 24, and 40 reveals that their authors are pairwise distinct; in fact, six such “quadruplets” can be identified in Table 1, rendering the existence of at least four authors as highly likely; see Supporting Information for details. Therefore, based on the statistical analysis, it can be deduced that there are at least four unique hands in the tested corpus. Our algorithmic observations can be further supplemented by the textual and archaeological context of the ostraca, deliberately avoided until this point. In particular, the prosaic lists of names in ostraca 31 and 39\(^*\) were most likely composed at Arad, as opposed to ostraca 7, 18, 24, and 40, which were probably dispatched from other locations.\(^*\) As per the table, ostraca 31 differs from both sides of ostraca 39; we can thus conjecture an existence of two additional authors, totaling at least six distinct writers.

**Discussion**

Identifying the military ranks of the authors can provide information regarding the spread of literacy within the Judahite army. Our proposed reconstruction of the hierarchical relations between the signees and the addressers of the examined inscriptions is as follows\(^*\) (see Fig. 4):

\(i\) The King of Judah: mentioned in ostraca 24 as dictating the overall military strategy

\(ii\) An unnamed military commander: the author of ostraca 24

\(iii\) Malkiyahu, the commander of the Arad fortress: mentioned in ostraca 24 and the recipient of ostraca 40\(^*\)

\(iv\) Eliashib, the quartermaster of the Arad fortress: the addressee of ostraca 1–16 and 18; mentioned in ostraca 17a; the writer of ostraca 31

\(v\) Eliashib’s subordinate: addressing Eliashib as “my lord” in ostraca 18

Following this reconstruction, it is reasonable to deduce the proliferation of literacy among the Judahite army ranks ca. 600 BCE. A contending claim that the ostraca were written by professional scribes can be dismissed with two arguments: the existence of two distinct writers in the tiny fortress of Arad (authors of ostraca 31 and 39) and the textual content of the inscriptions: Ostracon 1 orders the recipient (Eliashib) “write the name of the day,” ostraca 7 commands “and write it before you...,” and in ostraca 40 (reconstructions in refs. 6 and 18) the author mentions that he had written the letter. Thus, rather than implying the existence of scribes accompanying every Judahite official, the written evidence suggests a high degree of literacy in the entire Judahite chain of command.

The dissemination of writing within the Judahite army around 600 BCE is also confirmed by the existence of other military-related corpora of ostraca, at Horvat ‘Uza (19) and Tel Malhata (20) in the vicinity of Arad, and at Lachish\(^*\) in the Shephelah (summary in ref. 3)—all located on the borders of Judah (Fig. 1). We assume that in all these locations the situation was similar to Arad, with even the most mundane orders written down occasionally. In other words, the entire army apparatus, from high-ranking officials to humble vice-quartermasters of small desert outposts far from the center, was literate, in the sense of the ability to communicate in writing.

To support this bureaucratic apparatus, an appropriate educational system must have existed in Judah at the end of the first Temple period (2, 21–23). Additional evidence supporting writing awareness by the lowest echelons of society seems to come from the Mezad Hashavahu ostraca (24), which contains a complaint by a corvée worker against one of his overseers (most scholars agree that it was composed with the aid of a scribe).

Extrapolating the minimum of six authors in 16 Arad ostraca to the entire Arad corpus, to the whole military system in the southern Judahite frontier, to military posts in other sectors of the kingdom, to central administration towns such as Lachish, and to

---

\*Contrary to the excavator’s association of ostraca 31 and 39 with Stratum VII (ref. 6, also ref. 15) rather than VI where most of the examined ostraca were found, we agree with critics (16, 17) that these strata are in fact one and the same. Note that ostraca 31 was found in locus 779, alongside three seals of Eliashib (the addressee of ostraca 1–16 and 18, from Strata VII).

\*Ostraca 5, 7, 17a, 18, and 24 were most probably written in other locations (6). Ostraca 40 may have been written by troop commanders Gemaryahu and Nehemiyahu (see the following note) with some ties to Arad fortress; their names also appear at ostraca 31. This renders the common authorship of ostraca 31 and 40 unlikely. Furthermore, from Table 1, ostraca 40 and 39a have different authors.

\*We conjecture that the status of the officers who commanded the supplies to the Kitryim (the Greek or Cypriot mercenary unit), who wrote ostraca 1-8 and 17a, was similar to that of Malkiyahu (the commander of the fortress at Arad), and in any case they were Eliashib’s superiors. Also note that Gemaryahu and Nehemiyahu (ostraca 40) are Malkiyahu’s subordinates, whereas Hananyahu (author of ostraca 16, also mentioned in ostraca 3) is probably Eliashib’s counterpart in Beer Sheba. The textual content of the ostraca also suggests differentiation between combatant and logistics-oriented officials (Fig. 4).

\*Contrary to the excavator’s dating of ostraca 40 to Stratum VIII of the late 8th century (ref. 6, also ref. 17), it should probably be placed a century later, along with ostraca 24 (see ref. 18 for details). Note that a conflict between the vassal kingdoms of Judah and Edom, seemingly hinted at in this inscription, is unlikely under the strong rule of the Assyrian empire in the region (ca. 730–630 BCE), especially along the vitally important Arabian trade routes.

\*In fact, Lachish ostraca 3, also containing military correspondence, represents the most unambiguous evidence of a writing officer. The author seems offended by a suggestion that he is assisted by a scribe. See detail, including discussion regarding the literacy of army personnel, in ref. 2.
the capital, Jerusalem, a significant number of literate individuals can be assumed to have lived in Judah ca. 600 BCE.

The spread of literacy in late-monarchic Judah provides a possible stage setting for the compilation of literary works. True, biblical texts could have been written by a few and kept in seclusion in the Jerusalem Temple, and the illiterate populace could have been informed about them in public readings and verbal messages by these few (e.g., 2 Kings 23:2, referring to the period discussed here). However, widespread literacy offers a better background for the composition of ambitious works such as the Book of Deuteronomy and the history of Ancient Israel in the Books of Joshua to Kings (known as the Deuteronomistic History), which formed the platform for Judahite ideology and theology (e.g., ref. 25). Ideally, to deduce from literacy on the composition of literary (to differ from mundane) texts, we should have conducted comparative research on the centuries after the destruction of Jerusalem, a period when other biblical texts were written in both Jerusalem and Babylonia according to current textual research (e.g., refs. 1 and 26). However, in the Babylonian, Persian, and early Hellenistic periods, Jerusalem and the southern highlands show almost no evidence in the form of Hebrew inscriptions. In fact, not a single securely dated Hebrew inscription has been found in this territory for the period between 586 and ca. 350 BCE—no ostraca or a seal, a seal impression, or a bulla [the little that we know of this period is in Aramaic, the script of the newly present Persian empire (27)]. This should come as no surprise, because the destruction of Judah brought about the collapse of the kingdom’s bureaucracy and deportation of many of the literati. Still, for the centuries between ca. 600 and 200 BCE, the tension between current biblical exegesis (arguing for massive composition of texts) and the negative archaeological evidence remains unresolved.

Materials and Methods

This research was conducted on two datasets of written material. The main document assemblage was a corpus of 16 Hebrew ostraca inscriptions found at the Arad fortress (ca. 600 BCE). Table 1. Comparison between different Arad ostraca

# A few coins with Hebrew characters do appear between ca. 350 and 200 BCE.
images of these inscriptions. A second dataset, used to validate the algorithm, contained handwriting samples collected from 18 present-day writers of Modern Hebrew.

The aim of our main algorithm was to differentiate between writers in a given set of texts. This algorithm consisted of several stages. In the first step, character restoration, the image of the inscription was segmented into (often noisy) characters that were restored via a semiautomatic reconstruction procedure. The method was based on the representation of a character as a union of individual strokes that were treated independently and later recombined. The purpose of stroke restoration was to imitate a reed pen’s movement using several manually sampled key points. An optimization of the pen’s trajectory was performed for all intermediate sampled points. The restoration was conducted via the minimization of image energy functional, which took into account the adherence to the original image, the smoothness of the stroke, as well as certain properties of the reed radius. The minimization problem was solved by performing gradient descent iterations on a cubic-spline representation of the stroke. The end product of the reconstruction was a binary image of the character, incorporating all its strokes (see Figs. S1 and S2).

The second stage of the algorithm, letter comparison, relied on features extracted from the characters’ binary images, used to automatically compare characters from different texts. Several features were adapted, referring to aspects such as the character’s overall shape, the angles between strokes, the character’s center of gravity, as well as its horizontal and vertical projections. The features in use were SIFT (28), Zernike (29), DCT, K$_p$-tree (30), Image projections (31), L$_1$ and CMI (32). Additionally, for each feature, a respective distance was defined. Later on, all these distances were combined into a single, generalized feature vector. This vector described each character by its overall shape, the angles between strokes, the character’s s center of gravity, as well as its horizontal and vertical projections.

The experiment testing the $H_0$ performed a clustering on a set of letters from the two tested inscriptions (of specific type, e.g., aleph), disregarding their affiliation to either of the inscriptions. The clustering results should have resembled the original inscriptions if two different writers were present, while being random if this was not the case. Although this kind of test could have been performed on one specific letter, we could gain additional statistical significance if several different letters (e.g., aleph, he, tav, etc.) were present in the compared documents. Subsequently, several independent experiments were conducted (one for each letter), and their $P$ values were combined via the well-established Fisher’s method (33). The combination represented the probability that $H_0$ was true based on all of the evidence at our disposal (see PNAS Early Edition for details concerning various features in use).

The final stage of the algorithm addressed the main question, What is the probability that two given texts were written by the same author? This was achieved by posing an alternative null hypothesis $H_0$ (“both texts were written by the same author”) and attempting to reject it by conducting a relevant experiment. If its outcome was unlikely ($P \leq 0.2$), we rejected the $H_0$ and concluded that the documents were written by two individuals. Alternatively, if the occurrence of $H_0$ was probable ($P > 0.2$), we remained agnostic.

ACKNOWLEDGMENTS. This research was made possible by the dedicated work of Ms. Ma’ayan Mor. The kind assistance of Dr. Shirly Ben-Dor Evian, Ms. Sivan Einhorn, Ms. Noa Evron, Dr. Anat Mendel, Ms. Myrna Pollak, Mr. Michael Cordorsky, and Mr. Assaf Kleiman is greatly appreciated. We also thank the PNAS editor and the reviewers for their helpful comments and suggestions. A.S. thanks the Azrieli Foundation for the award of an Azrieli Fellowship. ---

1The Latin transliteration of the letter names differs slightly between Modern and Ancient Hebrew. For Ancient Hebrew, several spellings can be found in the literature: $aleph$, $aleph$, $bet$, $gimel$, $dalet$, $he$, $vav$, $zayin$, $het$, $tet$, $yod$, $kaf$, $lamed$, $mem$, $nun$, $samekh/samek$, $ayin/ain$, $pe$, $tsadi/Tsad$, $qof$, $resh$, $shin$, $tav$. For Modern Hebrew, the Unicode standard names are $alef$, $bet$, $gimel$, $dalet$, $he$, $vav$, $zayin$, $het$, $tet$, $yod$, $kaf$, $lamed$, $mem$, $nun$, $samekh/samek$, $ayin/ain$, $pe$, $tsadi/Tsad$, $qof$, $resh$, $shin$, $tav$. For simplicity’s sake, in what follows, we use the first orthography (without the diacritics) for each letter.
